We review recent developments in the study of deep inelastic scattering from light nuclei, focusing in particular on deuterium, helium, and lithium. Understanding the nuclear effects in these systems is essential for the extraction of information on the neutron structure function.

1. Introduction

For the past 20 years the nuclear EMC effect — the nuclear medium modification of the nucleon structure functions — has posed a serious challenge to models of the nucleus which involve quark degrees of freedom. Although the basic features of the EMC effect can be understood within a conventional nuclear physics framework, a quantitative description over the entire range of Bjorken- x appears beyond the capacity of a single mechanism. This has led to an assortment of nuclear models and effects which have been postulated to account for the medium modifications of the structure functions.

An impressive array of data on nuclear structure functions has by now been accumulated from experiments at CERN, SLAC, DESY (Hermes), Fermilab, Jefferson Lab and elsewhere, for a broad range of nuclei, and the quality of recent data exploring extreme kinematics, both at low x and high x , is pushing nuclear models to their limits. Surprisingly, the EMC effect in the lightest nuclei — in particular the $A = 2$ and $A = 3$ systems, where microscopic few-body calculations with realistic potentials are more feasible — is still unknown, leaving the determination of the A dependence of the effect incomplete. In addition, the absence of data on the EMC effect in deuterium and helium nuclei prevents the unambiguous determination of the structure function of the free neutron, for which these nuclei are often used as effective neutron targets.

Here we review the foundations of the conventional approach to deep

inelastic scattering (DIS) from few body nuclei, starting from a covariant, relativistic framework. We focus specifically on the intermediate and large x region dominated by valence quarks, and do not discuss the region of nuclear shadowing and antishadowing at $x < 0.1$. As examples, we describe the nuclear effects in spin-averaged and spin-dependent structure functions of the deuteron, the $A = 3$ mirror nuclei, and lithium isotopes, paying particular attention to the nuclear corrections which need to be applied when extracting neutron structure functions.

2. Formalism

Away from the small- x region ($x > 0.2 - 0.3$), DIS from a nucleus is computed in the nuclear impulse approximation in terms of incoherent scattering from individual bound nucleons in the nuclear target.^{1,2} The hadronic tensor for a nucleus A can be written as^{2,3}

$$W_{\mu\nu}^A(P, q) = \int d^4p \text{Tr} \left[\widehat{A}_{NA}(P, p) \cdot \widehat{W}_{\mu\nu}^N(p, q) \right] , \quad (1)$$

where P , p and q are the target nucleus, scattered nucleon, and photon momenta, respectively. For illustration we consider the case of spin-averaged DIS; the generalization to spin-dependent scattering is straightforward.^{4,5,6} In this case, the most general expression for the truncated (off-shell) nucleon tensor is given by²

$$\widehat{W}_{\mu\nu}^N(p, q) = g_{\mu\nu} \left(I \widehat{W}_0 + \not{p} \widehat{W}_1 + \not{q} \widehat{W}_2 \right) , \quad (2)$$

where the bound nucleon “structure functions” $\widehat{W}_{0,1,2}$ are functions of p and q , and the (off-shell) nucleon-nucleus amplitude can be written as

$$\widehat{A}_{NA}(P, p) = (I A_S + \gamma_\alpha A_V^\alpha) , \quad (3)$$

where a sum over residual $A - 1$ nuclear states is implicit in the functions A_S and A_V^α . The spin-averaged F_2 structure function of the nucleus is then given by

$$F_2^A(x) = \int d^4p \left(A_S \widehat{W}_0 + p \cdot A_V \widehat{W}_1 + q \cdot A_V \widehat{W}_2 \right) . \quad (4)$$

In general the nuclear structure function cannot be written as a one-dimensional convolution integral⁷ *even in the impulse approximation*: factorization of amplitudes does not imply factorization of structure functions.² However, by taking either selective on-shell^{2,8} or non-relativistic^{6,9} limits, one can identify a convolution component, plus off-shell ($p^2 \neq M^2$) corrections,

$$F_2^A(x) = \sum_N f_{N/A} \otimes F_2^N(x) + \delta^{(\text{off})} F_2^A(x) , \quad (5)$$

where $\otimes$ denotes convolution, $f_{N/A} \otimes F_2^N(x) \equiv \int dy f_{N/A}(y) F_2^N(x/y)$, with $y = p \cdot q / P \cdot q$ the light-cone fraction of the nucleus carried by the interacting nucleon.

3. Deuterium

Being the simplest nuclear system, the deuteron has been studied most extensively, both in non-relativistic and relativistic analyses. Within the formalism described in Section 2, the deuteron F_2 structure function can be calculated by smearing the nucleon structure functions with the nucleon light-cone momentum distribution in the deuteron, $f_{N/D}(y)$. The off-shell corrections can be evaluated in terms of the relativistic components of the deuteron wave functions and the p^2 dependence of the truncated nucleon structure functions,⁸ and are typically found to be rather small, $|\delta^{(\text{off})} F_2^D| \lesssim 1\%$ for all x .

Figure 1. Left panel: ratio of the deuteron to nucleon F_2 structure functions in the relativistic (off-shell) model⁸ (solid), and an on-shell model¹⁰ including Fermi motion only. Right panel: extracted neutron to proton ratio using the off-shell and on-shell models of the deuteron.¹¹

The calculated F_2^D structure function for the relativistic model, including the small off-shell correction, is shown in Fig. 1 (left panel) as a ratio to the free nucleon structure function (solid curve). Also shown is the result of an on-shell ansatz¹⁰ in which (effectively) only Fermi motion effects are included. This gives a much smaller EMC effect in the deuteron. From the measured deuteron and proton structure functions, and the smearing function, $f_{N/D}(y)$, one can extract the structure function of the neutron using the iterative deconvolution procedure^{12,13} (which does not assume

prior knowledge of F_2^n). Using F_2^p and F_2^D data from SLAC,¹⁴ the resulting F_2^n/F_2^p ratio is shown in Fig. 1 (right panel) for the relativistic^{11,15} and on-shell models (open and filled circles, respectively). The larger F_2^n/F_2^p values in the former reflect a larger EMC effect in the deuteron. Despite the deuteron being a loosely bound system, the nuclear effects at large x can therefore play an important role in the extraction of the free neutron structure function.

Figure 2. Ratio of deuteron and nucleon g_1 structure functions in the relativistic model⁴ (solid), and with a constant depolarization factor (dotted). Also shown is the ratio of the convolution component of g_1^D to the total (dashed).

A similar analysis can be performed for the spin-dependent g_1 structure function of the deuteron, in terms of the spin-dependent nucleon momentum distribution, $\Delta f_{N/D}(y)$, and relativistic (off-shell) corrections,⁴

$$g_1^D(x) = \sum_N \Delta f_{N/D} \otimes g_1^N(x) + \delta^{(\text{off})} g_1^D(x), \quad (6)$$

where $\Delta f_{N/D}$ is normalized to $\int dy \Delta f_{N/D}(y) = 1 - \frac{3}{2}\omega_D$, with ω_D the deuteron D state probability. The resulting ratio of the deuteron to nucleon g_1 structure functions is illustrated in Fig. 2. Also shown is the result assuming $\delta^{(\text{off})} g_1^D \rightarrow 0$ and $\Delta f_{N/D}(y) \rightarrow (1 - \frac{3}{2}\omega_D)\delta(1-y)$, in which the ratio is given by a constant depolarization factor for all x . For $x < 0.7$ the nuclear effects are weakly dependent on x , so that the use of a constant depolarization factor is a reasonable approximation, although it breaks down dramatically for $x > 0.75$. Furthermore, the convolution approximation is quite accurate for $x < 0.8$, with $\lesssim 1 - 2\%$ deviations from the full result.

The largest uncertainty in the extraction of g_1^n over this range of x is due to uncertainty in the D -state probability.

4. $A = 3$ Nuclei

As the lightest mirror nuclei, ${}^3\text{He}$ and ${}^3\text{H}$ provide a unique laboratory for studying nuclear effects in structure functions, since many of their properties are similar up to nuclear charge symmetry breaking effects. Furthermore, since the doubly represented nucleons tend to couple to spin 0, the spin of the $A = 3$ nuclei is carried largely by the singly represented nucleon (n in the case of ${}^3\text{He}$, p in the case of ${}^3\text{H}$).

At present the size of the nuclear EMC effect in ${}^3\text{H}$ is not known, and only scant data exist¹⁶ on the F_2 structure function of ${}^3\text{He}$ at lower Q^2 . The predicted nuclear EMC ratio for ${}^3\text{He}$,

$$R({}^3\text{He}) = \frac{F_2^{{}^3\text{He}}}{2F_2^p + F_2^n} , \quad (7)$$

is plotted in Fig. 3 (left panel), where $F_2^{{}^3\text{He}}$ is evaluated as in Eq. (5) via a convolution of the bound p and n structure functions with the nucleon momentum distributions in ${}^3\text{He}$, $f_{N/{}^3\text{He}}(y)$. The latter are obtained from three-body wave functions calculated by solving the Faddeev equations with a modified Paris potential¹⁷ (dashed) and via a variational approach^{18,19} (dot-dashed). Since relativistic wave functions of $A = 3$ nuclei are not yet available, we cannot quantify the off-shell correction, $\delta^{(\text{off})}F_2^{{}^3\text{He}}$. However, analysis of quasi-elastic scattering from ${}^4\text{He}$, in which binding effects are larger than those in ${}^3\text{He}$, suggests²⁰ rather small modifications in the intrinsic nucleon structure ($< 5\%$ for $x < 0.8$). The theoretical ratios are compared with data from HERMES¹⁶ on the ratio of ${}^3\text{He}$ to $D + p$ structure functions, and agree quite well within the current errors.²¹ The effect on $R({}^3\text{He})$ of including the EMC effect in the deuteron (solid) is relatively small for $x < 0.8$.

While the model dependence of the EMC effect in ${}^3\text{He}$ is at the few % level, the fact that ${}^3\text{He}$ and ${}^3\text{H}$ are mirror nuclei means that one can expect similar medium modification in both nuclei. This is illustrated in Fig. 3 (right panel), where the ratio of EMC ratios for ${}^3\text{He}$ and ${}^3\text{H}$, $\mathbf{R} \equiv R({}^3\text{He})/R({}^3\text{H})$, is plotted for the standard Faddeev wave function (solid),²² and a modified wave function including effects of charge symmetry breaking (dashed) which accounts for the difference in binding energies of ${}^3\text{He}$ and ${}^3\text{H}$. For comparison, the result of the density extrapolation model is also shown. Even though this model¹⁰ predicts a difference in the absolute size of the EMC effect between ${}^3\text{He}$ and ${}^3\text{H}$ of order 40%, it nevertheless gives

Figure 3. Left panel: nuclear EMC ratio in ^3He , compared with data on the $^3\text{He}/(D+p)$ ratio.¹⁶ The effect of nuclear corrections in the deuteron is indicated by the solid curve. Right panel: ratio of EMC ratios in ^3He and ^3H , for the Faddeev wave function model (solid), including explicit charge symmetry breaking effects (dashed),²² and an ansatz based on the nuclear density extrapolation model.²³

rise to a similar effect in the ratio $\mathbf{R}$.²³ From the calculated ratio $\mathbf{R}$ and a measurement of the ratio of the ^3He and ^3H structure functions, one can directly extract the neutron to proton ratio,²²

$$\frac{F_2^n}{F_2^p} = \frac{2\mathbf{R} - F_2^{^3\text{He}}/F_2^{^3\text{H}}}{2F_2^{^3\text{He}}/F_2^{^3\text{H}} - \mathbf{R}}, \quad (8)$$

with significantly less sensitivity to nuclear effects than in Fig. 1 using the inclusive deuteron data.^{22,24}

Turning to the spin polarized $A = 3$ system, the fact that in ^3He the pp pair couples predominantly to spin 0 allows polarized ^3He to be used as an effective polarized neutron target^{25,26}. The g_1 structure of ^3He can be written as

$$g_1^{^3\text{He}}(x) \approx 2\Delta f_{p/^3\text{He}} \otimes g_1^p(x) + \Delta f_{n/^3\text{He}} \otimes g_1^n(x), \quad (9)$$

where the spin-dependent nucleon momentum distributions in ^3He are normalized such that^{17,27} $\int dy \Delta f_{n/^3\text{He}}(y) \equiv \rho_n \approx 88\%$ and $\int dy \Delta f_{p/^3\text{He}}(y) \equiv \rho_p \approx -2\%$. The similarity between the ^3He and neutron g_1 structure functions is illustrated in Fig. 4 (left panel), reflecting the small proton contribution to the ^3He polarization. For a polarized ^3H target, the difference between the g_1 structure function of ^3H ,

$$g_1^{^3\text{H}}(x) \approx \Delta f_{p/^3\text{H}} \otimes g_1^p(x), \quad (10)$$

and g_1^p would be even smaller because, in addition to the small size of the neutron polarization in ^3H , the intrinsic magnitude of g_1^n is much smaller

than that of g_1^p . A measurement of $g_1^{^3\text{H}}$ would therefore allow an accurate determination of the $\Delta f_{p/^3\text{H}} \approx \Delta f_{n/^3\text{He}}$ distribution, which could then be used to minimize the uncertainty in the extraction of g_1^n from $g_1^{^3\text{He}}$. The effects of possible Δ resonance components in the ^3He wave function have also been examined by Bissey *et al.*²⁸

Figure 4. Left panel: xg_1 structure function of the neutron and ^3He . Right panel: neutron polarization asymmetry A_1^n obtained from the ^3He asymmetry including smearing corrections (solid), without smearing (dashed), and neglecting the proton polarization, $\rho_p = 0$ (dot-dashed).

Because the g_1^n structure function changes sign at intermediate x , it is not meaningful to calculate an EMC-type ratio. On the other hand, taking the ratio of the g_1 to F_1 structure functions (where $F_1 \approx F_2/2x$ at large Q^2), one can better visualize the nuclear corrections in the polarization asymmetry,

$$A_1(x) \approx \frac{g_1(x)}{F_1(x)}, \quad (11)$$

which is the quantity measured directly in polarized DIS experiments. In Fig. 4 (right panel) the A_1^n asymmetry is shown, extracted from the ^3He asymmetry including smearing corrections (solid). For comparison, the result without smearing is also shown (dashed) — in this case the distributions $\Delta f_{N/^3\text{He}}(y) \rightarrow \rho_N \delta(1-y)$, and the shapes of $g_1^{^3\text{He}}$ and g_1^n are assumed to be the same. This appears to be a reasonable approximation for $x < 0.7$, but breaks down beyond $x \sim 0.8$. Over the same region of x the proton polarization is also seen to play a relatively minor role, although it must be included if precision at the level of a few percent is required.

An accurate determination of nuclear effects is also necessary for the extraction of the g_2 structure function of the neutron. The g_2 structure function provides the cleanest means to access information on higher twist contributions in polarized DIS. Of particular importance is the x^2 -weighted moment of g_2 , which enters in the twist-3 d_2 matrix element. The nuclear corrections to the neutron g_2 structure function are illustrated in Fig. 5, where the x^2 -weighting emphasizes the larger- x region. Since there is practically no information on the twist-3 component of g_2 , the calculation has been performed assuming twist-2 dominance of g_2^n . The effect of smearing appears to be small, although not negligible, and needs to be included for an accurate determination of g_2^n at large x .

Figure 5. x^2 -weighted g_2 structure function of the neutron (solid), and of ^3He , including smearing corrections (dashed), and without smearing (dot-dashed).

5. Lithium

β -unstable Li isotopes provide a promising new avenue for exploring the quark structure of few body nuclei. The ^{11}Li nucleus, which is located at the neutron drip line, is believed to be well approximated as a ^9Li core plus two weakly bound valence neutrons, which form a halo structure. Because of the weak binding, it has been suggested²⁹ that the neutron momentum distribution in ^{11}Li should be very sharp and symmetric around $y = 1$, making it an excellent candidate for an effective neutron target. Polarized ^6Li nuclei, which have with spin 1 and isospin 0, have been suggested as effective polarized ($\approx 86\%$) deuteron targets, in the approximation that $\vec{^6\text{Li}} \approx \alpha + \vec{D}$. Furthermore, polarized $^{7,9,11}\text{Li}$ isotopes can also be used to study the novel structure function^{29,30} associated with spin 3/2 systems,

$\frac{3}{2}g_1$. Deep inelastic scattering from the ${}^7\text{Li}$ – ${}^7\text{Be}$ mirror nuclei can also be used to explore the medium modifications of the Bjorken and Gottfried sum rules.^{29,31} Studies with these nuclei may one day be undertaken at radioactive beam facilities, such as those proposed at RIKEN or GSI. The merits of using other nuclear targets, such as nitrogen, have been elaborated by Rondon.³²

6. Conclusions

The unprecedented quality of recent data on few body nuclear structure functions from new generations of accelerators is demanding better understanding of nuclei in extreme kinematic regions, such as at large x , where the effects of relativity and nucleon substructure play a more prominent role. This challenge is being met by concurrent progress being made in the theory of DIS from few body nuclei, especially deuterium and $A = 3$ nuclei.

In addition to more accurately determining the response of these nuclei to electromagnetic probes, an important practical necessity lies in controlling the nuclear corrections when extracting information on the structure of the neutron, for which light nuclei are often used as effective neutron targets. While much of the focus has been on the F_2 structure function, there is a growing need to understand the nuclear effects in other structure functions, such as g_1 and g_2 , as well as the new structure functions available for higher spin nuclei — both in the deep inelastic and resonance regions. The interplay between theoretical developments and anticipated future data promises to provide even deeper insights into the quark structure of nuclei.

Acknowledgments

We are grateful to F. Bissey and S. Liuti for providing their light-cone momentum distribution functions. This work was supported by the U.S. Department of Energy contract DE-AC05-84ER40150, under which the Southeastern Universities Research Association (SURA) operates the Thomas Jefferson National Accelerator Facility (Jefferson Lab) and by the Australian Research Council.
